

What Can We Say About Turkey and its Competitors in the EU Market? An Analysis by Extensive and Intensive  
Margins

## **I. Introduction**

One of the most challenging issues for developing countries is the need to reduce their dependence on traditional export products. In order to establish a more reliable basis for foreign exchange earnings and compete more successfully in international markets, not only increasing export earnings but also exporting new product varieties is required. Therefore, it is generally agreed that export diversification is a desirable practice, especially for developing countries, because it enhances export competitiveness by widening the set of variety of export products, thereby reducing dependence on traditional exports that have a long-term tendency of declining terms of trade. By means of regular and successful export diversification, countries can improve the overall terms of trade for their exports, minimize the conjectural fluctuations in export revenues and establish a more dynamic and reliable export sector. In this sense, export diversification and export competitiveness can be considered as two sides of the same coin. Therefore, export diversification, which can be attained by changing the share of existing commodities (intensive margin) and including new commodities in the export portfolio (extensive margin) is needed to raise competitiveness in the world markets.

In this study, we evaluate the degree of Turkey's export diversification in terms of the so-called extensive and intensive margins. Although the extensive and intensive margins have been defined in different ways by different studies, in our analysis we consider the extensive margin as a measure of the extension of the set of exported products through the addition of new export products over time. On the other side, the intensive margin is a measure of the intensity of the set of existing products that have been already exported in the previous time periods. More specifically, in this context, intensive margin refers to the share of products that are already being exported, while extensive margin refers to the share of new products in the export portfolio. We measure the relative significance of these margins in the context of the changes in Turkey's exports in the EU-15 market.

Turkey, in accordance with the world trend, has been adopting trade liberalization policies since the 1980s. In this process, the earlier 15 members of the EU (the EU-15 market hereafter) have traditionally been the most important trading partners of Turkey. Besides, the Customs Union between Turkey and the EU, which came into effect at the end of 1995, has been a turning point for Turkey in terms of a new regional-economic integration. However, previous studies show

that there is a well-established, difficult-to-change trade structure among the EU-15 countries themselves. Against this rigorous trade structure, it seems very difficult for Turkey to compete dynamically with the EU-15 countries in the EU-15 market, as Turkey's traditional competitiveness areas with respect to these well-developed countries are mostly raw-material- and labor-intensive products. Nevertheless, when the trade patterns between EU-15 and non-EU-15 countries which compete with Turkey in the EU-15 market such as Central and Eastern European Countries (CEECs), Middle Eastern and North African (MENA) countries, as well as certain countries from Asia, Africa, Latin America and also some from the developed world are examined, it is easier to observe a dynamic framework. For example, CEECs have generally been the most outstanding competitors in this market, especially after their accession to the EU in 2004 and 2007. MENA countries also have prominent export relations with the EU-15 countries. Certain Asian countries – led by China – have also considerably increased their exports to this market. On the other hand, the export shares of certain developed countries – such as the US, which is the most important trading partner of the EU – have decreased in recent years. This dynamic framework creates potential gains and promising competition possibilities for those countries with rational trade strategies. As an important exporter to the EU-15 market, Turkey has a special interest in enhancing export competitiveness in the EU-15 market in this very dynamic market.

Therefore, we evaluate Turkey's competitive position in the EU-15 market against its non-EU-15 competitors in terms of its extensive and intensive margins in this study. More specifically, we determine the extent to which the rise in Turkey's exports in the EU-15 market is attributable to increases in existing exports and to increases in new product varieties. Relying on our calculations, we compare Turkey to its main competitors in this market. Our research questions are: What has been the degree of effectiveness of extensive and intensive margins on the changes in Turkey's exports? Against which competitors and in which product categories does Turkey compete more dominantly in the new products and in the existing products?

With these questions in mind, we calculate the extensive and intensive margins for Turkey and its competitors in the EU-15 market for the period 1996-2006, in order to constitute a broad framework for comparative analysis. We also classify the export products into five groups according to their technological characteristics: Raw-material-intensive goods (RMIG), labor-

intensive goods (LIG), capital-intensive goods (CIG), easy-to-imitate research-intensive goods (EIRG) and difficult-to-imitate research-intensive goods (DIRG). We report our results also with respect to this technology-related classification.<sup>1</sup>

We first present the number of exported products for overall products along with the manufacturing and primary industries, according to technological categories in the initial and final years of analysis (i.e., 1996 and 2006). Then, we present our more detailed indexes and results, which we obtain by employing the methodologies developed by Feenstra and Kee (2007) and Amiti and Freund (2008).

To our knowledge, in the literature, there are no studies that have dealt with Turkey's competitiveness by using the important methodology of extensive-intensive margins. In this regard, this study is the first attempt to utilize these methodologies in the case of Turkey, along with a much broader set of sectors and a much more disaggregate data-set and thus covering an unprecedentedly large variety of products (i.e., at 5-digit level with 3049 products and 30 countries). More generally, we contribute to the empirical investigation of export diversification by providing new evidence based on intensive and extensive margins insofar as the main exporters to the EU-15 market are concerned. We hope that these new features of our analyses will not only enrich the existing empirical literature, but also provide an expanded choice set for export strategy possibilities.

## **II. Literature Review**

In this study, we evaluate Turkey's export diversification in conjunction with export competitiveness in terms of intensive and extensive margins<sup>2</sup>. Even though the review of the related literature shows that the extensive and intensive margins have been defined in different ways by different studies, the main and general idea here is to determine the degree of the contribution of the new and old products to the export growth of a country in a given market in a given period of time.

---

<sup>1</sup> In fact, we carried our analysis for each country with respect to the technology-related classification. However, we report our results only for Turkey by determining its rank among the other 30 countries. In some relevant connections, we evaluate the cases of other countries as well. That is to say, we are in a position to provide the results for each country upon request.

<sup>2</sup> For earlier studies involving alternative measures of export diversification and its evolution over time, with applications to Turkish foreign trade, see Erlat and Şahin (1998) and Erlat (1999).

In the literature, the studies that involve intensive-margin analysis originate from Armington's (1969) model of national differentiation. Such studies focus mainly upon the growth in the set of products that have already been exported previously. On the other hand, the studies that involve extensive-margin analysis originate from Krugman's (1980) monopolistic competitive model. Such studies consider only the growth in the set of new export-products. Recently, however, Hummels and Klenow (2005) argued that neither the Armington- nor the Krugman-model alone is successful enough in explaining the sources of export growth in a comprehensive way.

In the literature, the extensive margin is generally used to refer to the extent of new varieties of export products. Feenstra (1994) is one of the earlier and major studies that measure the growth in product variety over time. Incorporating product variety with the US import price index, he finds a strong evidence for the role of product variety growth in affecting this index. In this connection, some later studies that deal with product variety have utilized the Feenstra-index developed in Feenstra (1994). For example, Feenstra et al. (1999) analyze the effect of export variety on productivity in the case of South Korea's and Taiwan's exports to the US at the sector level between 1975 and 1991. They conclude that, in 9 of 16 export sectors, product variety has a significantly positive effect on productivity. Also, Feenstra and Kee (2007) compare the export variety of China and Mexico in the US market over the period 1989-2001 by using "The Harmonized Commodity Description and Coding System (HS)" 10 digit US import data. They find a significant increase in Mexico's export variety in all industries, especially after Mexico's admittance to the NAFTA. They find a significant increase in China's export variety as well. They conclude that China's export variety has recently exceeded that of Mexico in certain industries. Analogously, Feenstra and Kee (2006) relate export variety with productivity and they find that among the countries exporting to the US, the ones with higher export variety also have higher productivity. Funke and Ruhwedel (2001) find a positive correlation between the product variety of exports of 19 OECD countries to the US and their per-capita-income over the period 1989-1996. All these studies show that there is an important connection between the ability to export new products and productivity and hence competitiveness.

On the other hand, Hummels and Klenow (2005) examine both the extensive and intensive margins in a cross-country context for a given year. They develop extensive and intensive margins in order to see the cross-country differences between the exports of smaller and larger

economies in terms of quantity, quality and product variety. Using trade data for 110 exporter and 59 importer countries for the year 1995, Hummels and Klenow (2005) find that the extensive margin constitutes the bulk of the exports of larger economies. They also find that the intensive margin is affected more by higher quantities than higher prices. In the literature, many studies have followed and further developed Hummels and Klenow's (2005) framework of analysis. For example, Alvarez and Claro (2007) analyze the sources of China's export growth in Chilean markets. Their study is based on Hummels and Klenow's (2005) methodology of decomposing export growth into extensive and intensive margins and then decomposing further the intensive margin into price and quantity margins. They find that China's export growth is mainly due to the increase in the intensive margin. Yoshida (2008) also relies on the extensive and intensive margins, as developed by Hummels and Klenow (2005), as a determinant of intra-industry trade between Japan and Korea. He finds that the level of intra-industry trade is positively influenced by the introduction of new products and negatively affected by the increases in the trade of old products. Iranzo and Ma (2006) assess the extents to which China's influence on Mexico-US trade are due to extensive and intensive margins. Employing econometric estimation techniques, they find that China's exports to the US have adversely affected the volume of Mexico's existing products, while it has positively affected Mexico's new exports. Kandoğan (2006) compares the transition economies, i.e., formerly socialist countries from Central and Eastern Europe and Commonwealth of Independent States (CEECs and CIS), in terms of the extensive and intensive margins of their exports to the market economies over the years 1992-1999. Using a modified version of Hummels and Klenow's (2005) methodology, he finds that the increase in the intensive margin is much more important for CIS-exports, while the increase in the extensive margin is more significant for the exports of CEECs.

In this literature, one of the most important studies has been carried out by Besedes and Prusa (2007), who interpret the extensive margin as the ability of a country to obtain new export markets and the intensive margin as the ability to maintain the existing export relations. They decompose the intensive margin into surviving and deepening existing relations. Based on detailed export data for 46 developed and developing countries between 1975 and 2003, they conclude that developing countries have higher growth rates in the extensive margin as compared to the developed ones, while the opposite is valid in the case of the intensive margin. They also find that the developing countries lag behind the developed ones in terms of the

survival and deepening components. Finally, they conclude that differences across countries in terms of the extensive margin have a negligible impact on long-run export growth, while survival and deepening components have a considerable effect. Their results confirm Helpman, Melitz and Rubinstein (2007) and Felbermayr and Kohler (2006), who find that much of the trade growth is due to the intensive margin rather than the extensive margin.

Amurgo-Pacheco and Pierola (2007) add a geographical dimension to the classical product-definitions of the margins. They define the intensive margin in terms of “Old products being exported to Old Destinations” and the extensive margin in terms of three possibilities: “Old Products being exported to New Destinations”, “New Products to New Destinations” and “New Products to Old Destinations”. They find that the intensive margin is much more important than the extensive margin in the growth of trade for all countries in their sample. However, they also find that the relative importance of the extensive margin is higher for poorer regions relative to richer ones. Finally, they conclude that, at the extensive margin, geographical diversification is more important than product diversification.

Amiti and Freund (2008) decompose China’s export growth into its extensive and intensive margins for the period 1992-2006. Using HS-6-digit data, they reach an interesting result: Almost the entire growth of China’s exports to the world is due to the intensive margin. At HS-10-digit level, they find that the extensive margin is responsible for about 5-15 % of this growth.

With this related literature, our main objective is to distinguish between Turkey’s export-product categories, in which export growth can be explained more dominantly by the extensive and intensive margins.

### **III. Data, Methodology and Results**

Our data source in this study is “Eurostat” – the major statistical office of the European Union. Eurostat provides us with the necessary import figures of the EU-15 countries. We use import data of the EU-15 market, because it provides homogeneous customs values of imports coming from non-EU-15 countries. The Eurostat data-set was compiled in accordance with SITC Rev. 3 between 1996 and 2006; however, it was revised to Rev. 4 in 2007. As extensive-intensive margin computations would be severely affected from such re-classification, we were not able to use the data after 2006. Therefore, we had to confine our analysis to the period 1996-2006, using

SITC-Rev.3 data consistently throughout the entirety of our calculations. The data-set we use is at a quite disaggregate level, i.e. 5-digit, so as to take into account the potentially important effects of product heterogeneity in these types of analysis. More specifically, our analysis comprises 3049 products with 30 countries from Middle East and North Africa, Central and Eastern Europe, Asia, Latin America as well as some developed countries.

We present the results for overall (SITC 0-9), manufacturing (SITC 5-8) and primary (SITC 0-4) sectors, separately. We also report our results with respect to the technology-related classification.

We first count the number of export products along the period under consideration. Even though counting number of products is a practical and useful first step towards understanding the degree of export diversification, it alone is insufficient to see important details that cannot be overlooked. Therefore, we also analyze and evaluate the degree of export diversification in terms of shares, using some more technical methodologies. That is to say, secondly, we evaluate product varieties and extensive margins of the countries, based on the methodology of Feenstra and Kee (2007). This methodology is useful in measuring the importance of new products in terms of their share in the EU-15 market, and it also enables us to carry out cross-country comparisons. Finally, we measure the relative importance of extensive and intensive margins on the countries' own export growth in the EU-15 market from 1996 to 2006, based on the methodology of Amiti and Freund (2008).

### **III.i. The Number of the Types of Export-Products in the EU-15 market**

The most practical way of measuring the export-product variety of a country is to count the number of product categories that the country exports over time.

Table 1 below shows the number of the types of export-products in 1996 and 2006, in terms of (i) total number of products that each country exported to the EU-15 market and (ii) the percentage-ratio of these numbers in the total number of products exported to the EU-15 market by all the 30 countries considered. The ranking is according to the number of product-types for the overall industries in 2006.

**Table 1 Number of product types and percentage-share of each number in the total number of product types exported to the EU-15 market**

	OVERALL (SITC 0-9)				Manufacturing (SITC 5-8)				Primary (SITC 0-4)

Table 1 shows that the number of the types of export-products is the highest for the US in both 1996 and 2006. China's prominent success in increasing the types of its export-products from 1996 to 2006 is also noteworthy. Switzerland, Norway, Japan, Poland, the Czech Republic and

Canada had higher numbers of product types than China in 1996; however, China's number of product varieties is higher than all of these countries in 2006.

According to Table 1, for overall industries, Turkey was able to export 2205 and 2557 different products (at the 5-digit level) to the EU-15 market in 1996 and 2006, respectively. As of 2006, in terms of export diversification, Turkey's performance puts her at the 9th position (together with Canada) among the 30 exporters in the EU-15 market. In general, this can be considered a good performance.

Table 1 also demonstrates that, for overall industries, in 1996 and 2006, respectively, Turkey was able to export 70.1 % and 79.7 % of all types of products exported to the EU-15 market from the rest of the world. For the manufacturing industry, Turkey's performance in product variety is given by 74 % in 1996 and 85 % in 2006, while, for primary products, it is 57.4 % and 62.2 % in 1996 and 2006, respectively. That is to say, in terms of diversifying its exports, Turkey is structurally more successful in the manufacturing industry than in primary products. This can also be regarded as a promising result to some extent, because diversification in manufacturing can be considered a better sign of development, as compared to diversification in primary products. However, we should also note that product variety in manufacturing is higher than that in the overall and primary sectors for most of the countries.

In Table 2, we present a summary for Turkey in terms of each technological category. The first two blocks of the table show Turkey's number of product types and percentage-share of each number in the total number of product types exported to the EU-15 market in each technological category for 1996 and 2006, respectively. The last block shows Turkey's gains (i.e., increases) in its number of exported products from 1996 to 2006 for each technological category. The ranks indicate Turkey's position out of the 30 countries in our sample.

**Table 2 Number of products, shares and gain – Technological categories, Turkey**

TURKEY	1996			2006			Gain	
	Number	%	Rank	Number	%	Rank	Number	Rank
<b>RMIG</b>	375	55.6	9	411	61.2	10	36	21
<b>LIG</b>	809	86.0	11	887	91.7	5	78	11
<b>CIG</b>	240	63.0	14	310	79.9	10	70	5
<b>EIRG</b>	201	48.2	18	273	64.8	14	72	1
<b>DIRG</b>	580	79.5	14	676	89.1	9	96	4

According to Table 2, Turkey's performance in export diversification is best in the LIG category in both 1996 and 2006, as compared to the other four technological categories. More specifically, in the LIG category, Turkey exported 86 % of all types of products exported to the EU by the world in 1996 and 91.7 % in 2006. Turkey's lowest product variety is in the EIRG category in both 1996 and 2006, putting it in the 14th rank in 2006 among the 30 countries considered. Apparently, these results are not so hope-generating for Turkey, because they indicate that Turkey's patterns of export diversification tend to concentrate more in LIG, which can create quite small amounts of value added on the path of economic development, than in EIRG, which yield much higher amounts of value added. Fortunately, however, at this stage of our analysis, there is a reason to be optimistic about Turkey's performance in export diversification. That is to say, Turkey's position in DIRG, which can be considered the best type of export products in terms of creating the highest value added, is relatively better and more promising, as Turkey is placed in the 9th rank among the 30 exporters in 2006.

Table 2 also shows Turkey's gains in its number of exported products from 1996 to 2006 for each technological category. This set of computations provides us with a preliminary idea about the extensive margins of Turkey. The last block of the table presents our results in this regard. According to the table, for Turkey, the increase in the number of types of export-products is 36 in RMIG, 78 in LIG, 70 in CIG, 72 in EIRG and 96 in DIRG. Interestingly enough, in the DIRG category Turkey was ranked 4th among its 30 competitors, thanks to its inclusion of 96 types of new products between 1996 and 2006. Reasonably, if the DIRG category is considered to be the most important sector in terms of expanding development possibilities and improving export competitiveness in the long term, this result should be interpreted as a very positive outcome for Turkey's experience of export diversification in this period. That is to say, Turkey performed

much better than the overwhelming majority of its competitors in the EU-15 market in the 1996-2006 period, in terms of diversifying its exports of DIRG, which usually tend to create the highest value-added from exporting activity and the largest improvements in the terms-of-trade for the exporting country. What is more, Turkey is the top country in the EIRG category in terms of the increases in the number of exported products, with 72 new products being exported in 2006 as compared to 1996. That is to say, among the 30 exporters, Turkey is the most successful one in diversifying its exports of EIRG, which are presumably the second-best types of export-products for enhancing the level of development and degree of international competitiveness. However, as discussed in the context of the first two blocks of the table, Turkey's 2006-ranks for the EIRG is still quite low (i.e., 14th), despite its fine performance of export diversification in these categories from 1996 to 2006. Therefore, we can conclude that Turkey has still a long road to go to catch up with such developed countries as the US, Switzerland, Japan, Norway and Canada in terms of exporting as many research-intensive products as these countries actually sell in the EU-15 market. In this respect, a relatively more encouraging conclusion is also possible: In the post-2006 period, important opportunities seem to exist for Turkey, especially in the EIRG category and, to a slighter extent, in the DIRG category as well as in the CIG category, where Turkey ranks the 6th in terms of the increase in the number of new export-products.

Moreover, our computations for other countries also show that developing countries – especially Lithuania, Latvia, China, Romania and Ukraine along with Turkey – are the countries with the highest increases in the number of exported products from 1996 to 2006. In contrast, developed countries such as Switzerland, US, Japan, Canada and Norway are the ones with the lowest increases and in some cases with decreases in the number of the type of products exported to the EU-15 market. However, the magnitude of the losses for the developed countries is much lower than the magnitude of the gains for the developing countries, implying that the developing countries did not necessarily improve their product varieties at the expense of the developed countries. EU-15's overall demand for imports should have sufficiently and effectively increased so as to create extra opportunities for the developing countries from 1996 to 2006.

### **III.ii. Product Varieties and Extensive Margins (based on Feenstra and Kee, 2007)**

As we have already mentioned in the literature survey, most of the studies on extensive and intensive margins are based on Hummels and Klenow (2005). Hummels and Klenow (2005) decompose the market share of a country into its extensive and intensive margins at a point in time. In their methodology, extensive margin of a country measures the ratio of “the value of world exports of the products produced by this country” to “the value of world exports of all products produced by all countries.” However, there are some problems with this methodology. First, the value of the index depends on the set of products exported by the country-in-question, but not on its own value of exports. Hummels and Klenow (2005: 710) summarize the disadvantage concerning this problem as follows: “a country may appear to have a large extensive margin because it exports a small amount in categories in which the world exports a lot.” Secondly, as mentioned by Feenstra and Kee (2007), the application of this extensive-margin index in its original form leads to inconsistencies in cross-year comparisons. Feenstra and Kee (2007) overcome this problem by averaging the worldwide exports over the years. In this way, they obtain a consistent set of countries suitable for comparison. However, measuring the importance of intensive margin in the market share may be misleading, even after this modification. For this reason, we measure only the product varieties and extensive margin by the methodology of Feenstra and Kee (2007); and we utilize another index for the measurement of the intensive margin.

Based on the methodology by Feenstra and Kee (2007), first we measure product variety by the ratio of “the value of worldwide exports in products that a given country exports to the EU-15 market” to “the value of worldwide exports from all non-EU-15 countries to the EU-15 market.”

Formally:

$$PV_t^a = \frac{\sum_{j \in I_t^a} X_j^w}{\sum_{j \in I^w} X_j^w} \quad (1)$$

where  $PV_t^a$  refers to the product variety of “country  $a$ ” in year  $t$ ;  $j$  refers to the product;  $a$  refers to the country-in-question (e.g. Turkey);  $w$  refers to the world (i.e., all non-EU-15 countries exporting to the EU-15 market in our case);  $I_t^a$  refers to the set of products exported to the EU-15

market by “country  $a$ ” at time  $t$ ;  $I^w$  refers to the total set of worldwide products exported to the EU-15 market in the overall period and  $X_j^w$  is the *average value* of worldwide exports for product  $j$ , summed over all non-EU-15 countries and averaged across years. By summing across countries and averaging across years, we obtain a consistent comparison set of products exported by the world that does not itself vary over time.

The numerator in this expression is the value of worldwide exports in products that “country  $a$ ” exports to the EU-15 market, averaged over the years. The denominator is the worldwide exports from all non-EU-15 countries to the EU-15 market, which are also averaged over the years. Therefore,  $PV_t^a$  can be understood as world exports to the EU-15 market in  $I^a$  in year  $t$  relative to world exports to the EU-15 market in all  $I^w$ .

Then, the extensive margin of “country  $a$ ” ( $EM^a$ ) is defined as the growth rate of product variety from the year  $t_0$  to the year  $t_1$ , and computed by the following formula:

$$EM^a = [\ln(PV_{t_1}^a) - \ln(PV_{t_0}^a)] * 100 \quad (2)$$

Table 3 below presents the product varieties and extensive margins of the countries from 1996 to 2006 for overall, manufacturing and primary sectors. The ranking is based on the extensive margins. Bold numbers indicate the countries, compared to which Turkey is definitely more successful in the related sectors. Italic numbers show the countries with negative extensive margins.

Table 3 should be interpreted carefully. That is to say, product varieties and extensive margins should be considered together in making cross-country comparisons because considering only the extensive margin and taking it alone as a success indicator of exporting new products can be misleading. For example, in 1996, one country can have a very high product variety close to 100 percent and another country can have a very low product variety. In 2006, the first country can still have a very high product variety close to 100 percent and the second country might have increased its product variety remarkably. Given this pattern, let us suppose that the extensive margin for the first country turns out to be lower than that of the second country. In such a case, it can be misleading to conclude that the first country is definitely unsuccessful in exporting new products as compared to the second country. More accurately, it could be safely concluded that a

country is definitely more successful than one of its competitors in exporting new products if that country's product variety in 1996 and its extensive margin are both higher.

**Table 3 Product varieties and extensive margins, 1996 and 2006**

According to Table 3, Turkey's extensive margin is the highest among other countries when we consider overall sectors. In 1996, Turkey exported 74.8 percent of all types of products that the EU-15 countries imported. That percentage increased to 88.96 in 2006, indicating a growth rate of 17.33 percent (using the logarithmic growth formula given above). Latvia, Slovakia and Poland are the countries that follow Turkey. On the other hand, Japan, Israel, Russia, China, Thailand, Indonesia, Estonia and Canada are the countries that have negative extensive margins in the overall sectors. The extensive margin of the US has remained almost unchanged from

1996 to 2006 and it is also lower than that of the majority of the countries. However, the US is different from other countries because its product variety was already very high in 1996 (96.24 per cent), which, of course, limited its possibilities of growth in product variety and hence its extensive margin. Finally, Turkey's product variety in 1996 and also its extensive margin are both higher with respect to Tunisia, Slovenia, Slovakia, Lithuania, Romania, Malaysia, Bulgaria, Croatia, Latvia, Ukraine, Korea and Morocco. That is to say, in the case of overall sectors, Turkey is definitely more successful than these countries in exporting new products to the EU-15 market.

In the case of the manufacturing industry, Table 3 shows that all countries have increased their product variety from 1996 to 2006 except Switzerland, Hungary, Israel and Russia. Also, in 2006, product varieties are higher for China and developed countries like the U.S, Switzerland, Japan and Canada while extensive margins are higher for developing countries, especially for the small ones, such as Latvia, Ukraine, Lithuania and Romania. In manufacturing, Turkey's extensive margin is 3.52 percent, which is higher than that of Slovenia, Slovakia, Mexico and Bulgaria. As compared to these countries, Turkey's product variety in 1996 is also higher. Therefore, we can conclude for the manufacturing industry that Turkey is definitely more successful than these countries in terms of the ability to export new products to the EU-15 market. It should also be noted that Turkey is very similar to India in terms of product variety and extensive margin in the manufacturing industry. Moreover, China is one of the most successful countries in manufacturing in terms of exporting new products. China's product variety in 1996 is higher (94.06 per cent) than that of most countries, and its extensive margin is also higher than that of countries such as the Czech Republic, Poland, Brazil, Israel, Hungary, Turkey, India, etc.

Table 3 also shows that, for most of the countries, extensive margins in the primary sector are higher than those in the overall and manufacturing sectors. Most probably, this pattern is due to the fact that product varieties in the primary sector in 1996 were quite low for all countries, relative to those in overall and manufacturing sectors. This initial structural difference must have paved the way for higher growth in product variety in the primary sector from 1996 to 2006. In the primary sector, Slovakia has the highest extensive margin (87.9 percent). Turkey, Poland and Switzerland have also relatively higher extensive margins as compared to their competitors. On

the other hand, Indonesia, Thailand, Estonia, Canada and China are the countries that have the lowest extensive margins in the primary sector.

Next, we calculate and interpret the product varieties and extensive margins of Turkey from 1996 to 2006 according to the technological characteristics of the exported products. Table 4 below presents the results. The ranking is based on the extensive margins in each category out of 30 countries.

**Table 4 Product varieties and extensive margin – Technological categories, Turkey**

	Product Variety			
<b>TURKEY</b>	<b>1996</b>	<b>2006</b>	<b>EM</b>	<b>Rank</b>
<b>RMIG</b>	30.4	77.4	93.6	2
<b>LIG</b>	92.7	94.5	1.9	17
<b>CIG</b>	84.5	87.7	3.7	17
<b>EIRG</b>	89.1	93.8	5.2	7
<b>DIRG</b>	91.1	94.0	3.1	15

Based on Table 4, a general assessment of our results for Turkey's extensive margins in terms of the technological categories would go as follows: Due to a very low product variety in 1996 (30.4 %), Turkey's extensive margin in RMIG has turned out to be the second-highest among 30 major exporters in the EU-15 market. In terms of Turkey's performance in the extensive margin, EIRG, CIG and DIRG follow RMIG, respectively. On the other hand, Turkey's extensive margin is the lowest in LIG and this result occurred mainly due to the fact that Turkey's product variety in LIG in 1996 was already quite high (92.7 %); indeed, it was the highest product variety for Turkey among the five technological categories. Although there are not considerably large differences in Turkey's extensive margins in the EIRG, CIG and DIRG categories, Turkey is even more successful in the EIRG than in the CIG category, since its product variety in EIRG in 1996 was higher than that in CIG and also its extensive margin is higher in EIRG than in CIG. This relative success in EIRG on the part of Turkey can be considered an encouraging result, as it is usually desirable for any developing country to diversify successfully its exports of research-intensive goods on the way to improving international competitiveness and expanding development possibilities. Also, Turkey's success in the relatively high-tech products (i.e., EIRG and DIRG) should not be underestimated, because Turkey's product variety in these two

categories was also rather high in 1996 (89.1% and 91.1% for EIRG and DIRG, respectively). In other words, Turkey has exhibited a good performance in export diversification, as it seems to have been breaking its dependence on the traditional labor-intensive products and channeling its exporting capability increasingly more towards relatively high-tech products, as well as capital-intensive ones. Of course, these are desirable results for a developing country striving for enhancements in its international competitiveness.

### **III.iii. Extensive and Intensive Margins of Export Growth (based on Amiti and Freund, 2008)**

Unlike the previous index, both the extensive and intensive margins of a country depend only on the value of its own exports in the index developed by Amiti and Freund (2008), who construct extensive and intensive margins of a country's export growth. In other words, it does not take into account the shares in the import market. So, the decomposition by Amiti and Freund (2008) is useful for analyzing the export growth of a country over time, rather than cross-country comparisons. Hence, the methodology developed by Amiti and Freund (2008) should not be confused with the methodology developed by Feenstra and Kee (2007).

Amiti and Freund (2008) decompose export growth of a country from one year to another into three parts: i) the increase in the export growth due to the growth in products that were exported in both years (intensive margin), ii) the contraction in export growth due to products exported in the base year but no longer exported in the final year (disappearing goods) and iii) the increase in export growth due to the export of new products (new goods). They define the extensive margin as 'the new-goods component' minus 'the disappearing-goods component'. At this point, we should note that Amiti and Freund (2008) is the first study to introduce disappearing goods into the definition of the extensive margin.

Formally, Amiti and Freund (2008) decompose export growth of a country from one year to the next into its extensive and intensive margins as follows:

$$\underbrace{\frac{\sum_j X_{t,j} - \sum_j X_{t-1,j}}{\sum_j X_{t-1,j}}}_{\text{Export Growth}} = \underbrace{\frac{\sum_{j \in I} X_{t,j} - \sum_{j \in I} X_{t-1,j}}{\sum_j X_{t-1,j}}}_{\text{(i) Intensive Margin}} + \underbrace{\frac{\sum_{j \in I_t^N} X_{t,j}}{\sum_j X_{t-1,j}}}_{\text{(ii) Extensive Margin}} - \underbrace{\frac{\sum_{j \in I_t^D} X_{t-1,j}}{\sum_j X_{t-1,j}}}_{\text{(iii)}} \quad (3)$$

where  $I_t^N$  is the set of products exported by the country in the year  $t$  but not exported in the year  $t-1$  (new products);  $I_{t-1}^D$  is the set of products exported in the year  $t-1$  but not exported in the year  $t$  (disappearing products);  $I$  is the set of products exported in both the year  $t$  and the year  $t-1$ ;  $X_{t,j}$  and  $X_{t-1,j}$  are values of the exports of “product  $j$ ” in the year  $t$  and the year  $t-1$ , respectively.

Therefore, as in Amiti and Freund (2008), we decompose export growth of a country from 1996 to 2006 into three parts:

(i) the growth in products that were exported in both periods, which they call “the intensive margin”;

(ii) the increase in export growth due to the new products

(iii) the decrease in export growth due to the disappearing goods. Extensive margin is defined as the component (ii) minus component (iii).

Table 5 below presents the export growth of the countries from 1996 to 2006 and the share of export growth attributed to the intensive and extensive margins for the overall, manufacturing and primary sectors, respectively. The ranking is according to the export growth for the overall sectors.

According to the table, Turkey’s export growth rate is 254% in the overall sectors and 290% in manufacturing. In all categories, such MENA countries as Morocco and Tunisia, and such Asian countries as India and Indonesia have lower rates of export growth than Turkey. In general, China and the CEECs have higher rates of export growth than Turkey in overall and manufacturing sectors. Considering the extensive and intensive margins of export growth, the

tables show that a large proportion of the export growth of all countries arises from their intensive margins.

Interestingly, in overall sectors, Canada's extensive margin is the highest (33%), whereas the previous index showed that Canada is the least successful country in exporting new products. The reason why Canada has the highest extensive margin according to the Amiti and Freund (2008) index can be explained as follows: In overall sectors, there is a product with code 99908, which was exported by Canada for the first time in 2006. However, product 99908 is registered as "confidential trade" in Eurostat. Even though this product constitutes a high proportion of Canada's total exports (7%), the share of this product in total imports of EU-15 is nearly zero percent. Therefore, in the Amiti and Freund index, -which is based only on the own exports of the country, Canada's extensive margin turns out to be the highest, while it is the smallest according to the Feenstra and Kee (2007) index. Following Canada, Lithuania (23%), India (13%) and Morocco (12%) are the other countries with the highest extensive margins in overall sectors. The U.S (-7%), Russia (-3%), Norway (-4%) and Switzerland (-1%) have negative extensive margins due to disappearing goods from 1996 to 2006.

Rather similar to the cases of Romania and Taiwan, Turkey's extensive margin is 4% in overall sectors. According to the Feenstra and Kee (2007) index, Turkey's extensive margin was the highest in overall sectors; however, according to the Amiti and Freund (2008) index, Turkey is ranked 16th. The reason for this big difference is that, in 2006, Turkey exported a relatively small amount in categories in which the world exported a lot to the EU-15 market.

In the manufacturing sector, the effect of disappearing products on the extensive margin is generally much lower, as compared to the overall sectors. In manufacturing, only 2% of Turkey's export growth is due to the extensive margin, which results completely from new products. Canada (24%), Lithuania (15%) and Ukraine (8%) have the top-three extensive margins in manufacturing.

Relative to the overall and manufacturing sectors, the extensive margin in the primary sector is the highest for most of the countries (Table 5). 23% of Turkey's export growth in the primary sector is due to the extensive margin, which is completely due to new products. India (62%),

Croatia (47%) and Slovenia (37%) are the leading countries in the primary-sector exports in terms of their extensive margins.

**Table 5 Intensive and Extensive Margins (based on Amiti and Freund, 2008)**

Next, we calculate the extensive and intensive margins of Turkey according to technological categories. Table 6 presents the results, where the ranking is based on the export growth for overall sectors.

**Table 6 Extensive and Intensive Margins of the Export Growth, Technological categories, Turkey**

			<b>Amiti and Freund Index</b>			
<b>TURKEY</b>	Export Growth	Rank	Intensive Margin	Extensive Margin	<i>New Product</i>	<i>Disapp. Products</i>
<b>RMIG</b>	123	17	0.75	0.25	<i>0.25</i>	<i>0.00</i>
<b>LIG</b>	154	9	1.00	0.00	<i>0.00</i>	<i>0.00</i>
<b>CIG</b>	940	2	0.99	0.01	<i>0.01</i>	<i>0.00</i>
<b>EIRG</b>	702	6	0.99	0.01	<i>0.02</i>	<i>0.01</i>
<b>DIRG</b>	253	13	0.93	0.07	<i>0.10</i>	<i>0.02</i>

According to Table 6, among other categories, Turkey's rate of export growth is the highest in the CIG category (940%) and 99 % of this growth comes from the intensive margin, hence only 1% from the extensive margin. This 1% arises completely from new products. The EIRG category (702%) follows CIG and again only 1% of this growth comes from the extensive margin. New products lead to a 2% contribution to this growth, whereas disappearing goods cause a 1% decrease. In the DIRG category, Turkey's rate of export growth is 253% and 7% of this growth comes from the extensive margin. New products lead to a 10% increase, while disappearing goods cause a 3% decrease. In the LIG category, Turkey's rate of export growth is 154%. All of this growth comes from the intensive margin. Finally, in the RMIG category, Turkey's export growth is the lowest (123%), while its extensive margin is the highest (25%). All in all, we can conclude that a far greater portion of Turkey's export growth is due to the intensive margin, rather than the extensive margin. As we mentioned in the previous case, a relatively higher extensive margin in the RMIG category is a natural result since Turkey's product variety was very low in 1996. On the other hand, in DIRG, Turkey is quite successful in exporting new products, as compared to other categories. In CIG, while the export growth is very high, we observe that this growth has not been supported by new product varieties. For other countries, the extensive margins are relatively higher, such as China with 19%. In this regard, Turkey seems to have fallen behind its competitors in terms of producing and exporting new products.

#### **IV. Conclusions**

In this study, we evaluated Turkey's export diversification in terms of extensive and intensive margins and constructed a framework of analysis for comparing Turkey with its main competitors in the EU-15 market. We first calculated and assessed the number of products exported to this market by each country in 1996 and 2006, since changes in the number of exported products give a preliminary idea on the extensive margins of the countries. Then, we analyzed the extensive and intensive margins in terms of export shares by using more sophisticated methodologies. First, we examined the extensive margins of all countries over time, based on the methodologies developed by Hummels and Klenow (2005) and Feenstra and Kee (2007). In this regard, we evaluated the importance of new products in terms of their shares in the EU-15 market. Secondly, based on Amiti and Freund (2008), we measured the relative importance of extensive and intensive margins on Turkey's export growth in the EU-15 market from 1996 to 2006 and compared it with Turkey's main competitors in this market. In this way, we assessed the importance of new products in terms of their shares in countries' own exports.

One of our major results is that the much larger portions of export growth are generally due to the intensive margin (rather than to the extensive margin) for all countries. Also our computations demonstrated that product varieties are especially higher for China and such developed countries as the U.S, Switzerland, Japan and Canada, while the extensive margins are generally higher for the developing countries, especially for the small ones like Latvia, Ukraine, Lithuania and Romania. China's performance in export diversification in terms of adding new products to its export portfolio is also very impressive.

When we analyze the dynamics in the EU-15 market from a broader perspective that involves a comparison of developed countries vis-à-vis the developing countries, our results indicate that the latter's position has generally improved better than that of the former. That is to say, the relative importance of the exports of the developing countries has been increasing regularly in the EU-15 market in our period of analysis. Indeed, this relative rise of the developing countries against the developed ones has been a general trend at the global level and the reflections of this trend in the EU-15 market are quite prominent. For example, there are decreases in the number of the product types exported from the developed countries to the EU-15 market, while the developing countries exhibited increases in this respect. However, the gains of the developing

countries are much higher than the losses of the developed countries. That is to say, the improvement on the part of the developing countries has not been necessarily at the expense of the developed countries. The upshot is that demand for imports by the EU-15 countries has increased in a dynamic pace, generating further export possibilities for the developing countries, including Turkey, from 1996 to 2006.

From Turkey's point of view, according to the three types of extensive-intensive margins measurement (i.e., the number of exported products, Feenstra and Kee and Amiti and Freund), in the RMIG category, Turkey's ability to export new products seems quite successful. In 1996, although the number of products exported by Turkey is not very low, the share of world exports of these products in the total world exports is very small. However, Turkey has overcome this drawback to a large extent as of 2006, presumably due to Turkish exporters' correct choices of new products and the high share of these products both in the EU-15 market and in Turkey's own exports. In LIG, the number of products that are already being exported by Turkey as well as the world export share of these products in total world exports to the EU-15 are higher, as compared to other categories in 1996. This structural aspect of the LIG category has limited the increase in Turkey's extensive margin. In both EIRG and CIG, Turkey exhibited a successful performance in terms of exporting new products from 1996 to 2006, as based on our results obtained through the methodology developed by Feenstra and Kee (2007). However, the Amiti and Freund (2008) index shows that the extensive margin is very small in these categories. In other words, there are new products exported by Turkey to the EU-15 market and the share of world's exports of these products in EU-15's total imports increased remarkably. However, Amiti and Freund (2008) index shows that these new products lead to an infinitesimal increase in Turkey's own export growth. In DIRG, Turkey is also quite successful in terms of its ability to export new products, based on all the three criteria.

Consequently, the new products produced and exported by Turkey from 1996 to 2006 seem to be correct choices for improving its competitiveness. Turkey has opportunities to raise its export growth as well as its competitiveness in the EU-15 market by increasing the production and exports of these new products. However, it should also be noted that if Turkey continues to export these new products at the existing relatively low levels, its competitiveness will not improve at all. If Turkey has unsurpassable difficulties to achieve an increase in the exports of

these new products, a second-best choice can be re-allocating resources to the production of the “old” products that have already been exported previously.

All in all, Turkey is especially successful in diversifying its export-products in CIG, EIRG and DIRG categories for which the EU-15-demand for imports from the rest of the world has been in ascendancy. Therefore, focusing upon its exporting capability in the context of the EU-15 market, Turkey can be said to be successful in exporting new products. For the future, there seem be further opportunities to enhance its ability to diversify its exports and hence its competitiveness.
